%                               Homework - August 4
%
% We are faced here with finding not just a root of the given equation,
%but the smallest positive root. We must thus study the equation and decide
%how we can tell if we have the correct root. Meditate on the secant function.
%At 0, it is 1, and it increases without bound on the interval (0, pi/2). A
%bit of reflection should convince you that our problem has exactly one root
%on the interval from zero to where the argument of the secant is pi/2, or
%where (L/2)*sqrt(x/E)=pi/2. In other words, where x=E*(pi/L)^2. We shall call
%this the "critical value." If we find a positive root less than this critical
%value, it must be the one we seek. A root larger than this is not one we seek.
%
% To make some of the algebra a bit simpler, I set t=sqrt(x/E), and solved
%for t. I used Newton's method, modified slightly to force the iterates to stay
%below the critical value. I hope my code is reasonably clear. Here it is:
```

```
»type s
```

```
ul=pi/L;
t=ul/1.5; mm=1000;
k=1; T=[t];
while k<20 & abs(mm) > 1E-10
    mm=del(t, L, e);
    t=t-mm;
    if t > ul
        t=(t+mm+ul)/2;
    end
    k=k+1;
end
[e L E*ul^2 E*t^2 ]
```

```
»type del
```

```
function y=del(t, L, e)
    K=4/3E3; arg=L*t/2;
    top=t^2-K/(1+e*sec(arg));
    bottom=2*t+(K*e*L/2)*(sec(arg)*tan(arg))/(1+e*sec(arg))^2;
    y=top/bottom;
```

```
»%Here are the computations. Note that each line gives e, L, the critical value
»%and the desired root.
```
